

The Simplex Method

Eklavya Sharma

This document describes the *simplex method* for solving linear programs. The following result (proof omitted for brevity) will help us focus on a special case of linear programming.

1 Preliminaries

Theorem 1. *Any linear programming problem can be reduced to the following problem (called a standard form linear program):*

$$\min_{x \in \mathbb{R}^n} c^T x \text{ where } Ax = b \text{ and } x \geq 0.$$

Here $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$ and $c \in \mathbb{R}^n$.

We will also assume without loss of generality that $\text{rank}(A) = m$.

Read the following concepts at TheoremDep (<https://sharmaeklavya2.github.io/theoremdep/>):

- Basic feasible solution (BFS)
- Extreme point of a convex set
- Extreme point iff BFS
- LP in orthant is optimized at BFS

Due to the last point above, we will focus on finding an optimal solution that is also a BFS.

Lemma 2. *Let $B = [u_1, u_2, \dots, u_n]$ be a basis of a vector space V . Let $w = \sum_{i=1}^n \lambda_i u_i$. Then $B' = B - \{u_r\} \cup \{w\}$ is a basis of V iff $\lambda_r \neq 0$.*

Proof. (See <https://sharmaeklavya2.github.io/theoremdep/nodes/linear-algebra/vector-spaces/basis/replace-vector.html>.) □

Lemma 3. *For any matrix A , we have $\text{rank}(A) = \text{rank}(A^T)$.*

Proof. (TODO: find proof) □

1.1 Notation

For any non-negative integer n , let $[n] := \{1, 2, \dots, n\}$ (or $[n] := [1, 2, \dots, n]$, depending on the context).

Let $v \in \mathbb{R}^n$ and $A \in \mathbb{R}^{m \times n}$. Let $i \in [m]$ and $j \in [n]$. Then the j^{th} element of v is denoted as v_j or $v[j]$. The element of A in the i^{th} row and j^{th} column of A is denoted as $A_{i,j}$ or $A[i, j]$. $A[:, j]$ denotes the j^{th} column of A and $A[i, :]$ denotes the i^{th} row of A .

Let $J = [j_1, j_2, \dots, j_r]$ be a sequence of r integers in $[n]$. $v[J]$ is defined as the vector $[v[j_1], v[j_2], \dots, v[j_r]]$. $A[:, J]$ is defined as the matrix whose k^{th} column is $A[:, j_k]$. Let $K = [k_1, k_2, \dots, k_q]$ be a sequence of q integers in $[m]$. Then $A[K, :]$ is defined as the matrix whose i^{th} column is $A[k_i, :]$.

For matrices $A \in \mathbb{R}^{m \times n_1}$ and $B \in \mathbb{R}^{m \times n_2}$, let $C = [A, B]$ denote the matrix in $\mathbb{R}^{m \times (n_1 + n_2)}$ where the first n_1 columns in C are the columns of A and the last n_2 columns in C are the columns of B . We call C the *horizontal concatenation* of A and B . We can similarly define horizontal concatenation of more than two matrices. We can similarly define vertical concatenation of A and B , which we denote as $\begin{bmatrix} A \\ B \end{bmatrix}$.

2 Bases

Consider this linear program:

$$\min_{x \in \mathbb{R}^n} c^T x \text{ where } Ax = b \text{ and } x \geq 0.$$

Here $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$ and $c \in \mathbb{R}^n$.

Definition 1 (Basis). Let J be a sequence of m distinct numbers from $[n]$. Let $B := A[:, J]$. Then J is called a *basis* of the LP iff $\text{rank}(B) = m$. J is called a *feasible basis* iff it is a basis and $B^{-1}b \geq 0$.

Let \bar{J} be the increasing sequence of values of $[n]$ that are not in J . Define $\text{solve}(J)$ as a vector $\hat{x} \in \mathbb{R}^n$, where $\hat{x}[J] = B^{-1}b$ and $\hat{x}[\bar{J}] = 0$.

The following two results show that to find an optimal BFS of the LP, we can find a feasible basis J that minimizes $c^T \text{solve}(J)$, and then return $\text{solve}(J)$.

Lemma 4. Let J be a feasible basis and $\hat{x} = \text{solve}(J)$. Then \hat{x} is a BFS of the LP.

Proof. It's trivial to see that $\hat{x} \geq 0$. Let $B = A[:, J]$ and $N = A[:, \bar{J}]$. Then

$$A\hat{x} = B\hat{x}[J] + N\hat{x}[\bar{J}] = B(B^{-1}b) = b.$$

Hence, \hat{x} is feasible for the LP.

Because we can rearrange variables and constraints, we can assume without loss of generality that $J = [m]$. The equality constraints are tight, and their coefficient matrix is $A = [B, N]$. The non-negativity constraints $\{x_j \geq 0 : j \in \bar{J}\}$ are tight, and their coefficient matrix is $I_n[\bar{J}, :] = [0, I_{n-m}]$, where I_k denotes the k -by- k identity matrix. Hence, the rank of the coefficient matrix of tight constraints at \hat{x} is

$$\text{rank} \left(\begin{bmatrix} B & N \\ 0 & I_{n-m} \end{bmatrix} \right) = \text{rank} \left(\begin{bmatrix} B & 0 \\ 0 & I_{n-m} \end{bmatrix} \right) = \text{rank}(B) + (n - m) = n.$$

The first equation follows from the fact that rank is unaffected by row operations. The third equation follows from the fact that J is a basis. Since the coefficient matrix of tight constraints of \hat{x} has rank n , \hat{x} is a BFS of the LP. \square

Lemma 5. Let \hat{x} be a BFS of the LP. Then there exists a feasible basis J such that $\hat{x} = \text{solve}(J)$.

Proof. Since \hat{x} is a BFS, there exist n linearly independent constraints that are tight at \hat{x} . m of these are the equality constraints, whose coefficient matrix is A . The rest are inequality constraints. Let \bar{J} be the indices of these $n - m$ inequality constraints. This implies $\hat{x}[\bar{J}] = 0$. Since we can rearrange variables, assume without loss of generality that $\bar{J} = [m+1, m+2, \dots, n]$. The coefficient matrix of these constraints is $I_n[\bar{J}, *] = [0, I_{n-m}]$.

Let $J = [m]$. Let $B = A[*, J]$ and $N = A[*, \bar{J}]$. Then $A = [B, N]$. Since \hat{x} is a BFS, we get

$$n = \text{rank} \left(\begin{bmatrix} B & N \\ 0 & I_{n-m} \end{bmatrix} \right) = \text{rank} \left(\begin{bmatrix} B & 0 \\ 0 & I_{n-m} \end{bmatrix} \right) = \text{rank}(B) + (n - m).$$

This implies that $\text{rank}(B) = m$, which shows that J is a basis of the LP.

Furthermore, since \hat{x} is feasible for the LP, we get that $b = A\hat{x} = B\hat{x}[J] + N\hat{x}[\bar{J}] = B\hat{x}[J]$. Hence, $\hat{x}[J] = B^{-1}b$. Since \hat{x} is feasible for the LP, we get $\hat{x} \geq 0 \implies \hat{x}[J] \geq 0 \implies B^{-1}b \geq 0$. Hence, J is a feasible basis and $\text{solve}(J) = \hat{x}$. \square

3 The Simplex Algorithm

Algorithm 1 naiveSimplex(A, b, c, J): Here $A \in \mathbb{R}^{m \times n}$ and J is a feasible basis for the standard LP given by A, b, c .

```

1: while true do
2:    $B = A[*, J]$ 
3:    $Y = B^{-1}A$  // If B isn't invertible, throw an exception
4:    $\bar{b} = B^{-1}b$ 
5:   assert( $\bar{b} \geq 0$ )
6:    $z = Y^T c[J]$ 
7:   if  $c - z \geq 0$  then
8:     return (optimal,  $\text{solve}(J)$ )
9:   end if
10:  Find  $k \in [n]$  such that  $c_k - z_k < 0$ .
11:  Define  $y \in \mathbb{R}^n$  as  $y_t = \begin{cases} -Y[i, k] & \text{if } t = j_i \\ 1 & \text{if } t = k \\ 0 & \text{otherwise} \end{cases}$ .
12:  if  $Y[*, k] \leq 0$  then
13:    return (unbounded,  $\text{solve}(J), y$ ), where
14:  end if
15:   $r = \underset{i \in [m]: Y[i, k] > 0}{\text{argmin}} \frac{\bar{b}_i}{Y[i, k]}$ 
16:   $\delta = \bar{b}_r / Y[r, k]$ 
17:   $J[r] = k$  // change the  $r^{\text{th}}$  entry in  $J$  to  $k$ .
18: end while

```

Theorem 6. If `naiveSimplex` outputs $(\text{optimal}, \hat{x})$, then \hat{x} is a BFS of the LP and an optimal solution to the LP.

Proof. If `naiveSimplex` outputs $(\text{optimal}, \hat{x})$ in an iteration, then the algorithm didn't fail at Lines 3 and 5, so $\text{rank}(B) = m$ and $\bar{b} \geq 0$ in that iteration. This implies that J is a feasible basis in that iteration. Hence, by Lemma 4, $\hat{x} = \text{solve}(J)$ is a BFS of the LP. Note that $c^T \hat{x} = c[J]^T \hat{x}[J] = c[J]^T \bar{b}$.

Let $\bar{J} = [n] - J$. Let $N = A[\ast, \bar{J}]$. Let $x_B = x[J]$ and $x_N = x[\bar{J}]$. Then

$$Ax = b \iff Bx_B + Nx_N = b \iff x_B = \bar{b} - B^{-1}Nx_N.$$

Note that since the constraint $x_B = \bar{b} - B^{-1}Nx_N$ is equivalent to $Ax = b$, we can replace $Ax = b$ by $x_B = \bar{b} - B^{-1}Nx_N$ in the LP without affecting the set of feasible solutions.

We can use these new constraints to express the objective value as a function of x_N .

$$\begin{aligned} c^T x &= c[J]^T x_B + c[\bar{J}]^T x_N \\ &= c[J]^T (\bar{b} - B^{-1}Nx_N) + c[\bar{J}]^T x_N \\ &= c[J]^T \bar{b} + (c[\bar{J}]^T - c[J]^T B^{-1}N)x_N \end{aligned}$$

$$z[\bar{J}]^T = (c[J]^T Y)[\bar{J}] = c[J]^T B^{-1}A[\ast, \bar{J}] = c[J]^T B^{-1}N.$$

$$\implies c^T x = c[J]^T \bar{b} + (c - z)[\bar{J}]^T x_N.$$

From the non-negativity constraints, we know that $x_N \geq 0$. We also know that $c - z \geq 0$, since `naiveSimplex` returned $(\text{optimal}, \hat{x})$. Hence, for every feasible x , we have $c^T x = c[J]^T \bar{b} + (c - z)[\bar{J}]^T x_N \geq c[J]^T \bar{b} = c^T \hat{x}$. Hence, \hat{x} is an optimal solution to the LP. \square

Lemma 7. $z[J] = c[J]$ (before J changes at Line 17).

Proof.

$$z[J]^T = c[J]^T (B^{-1}A)[\ast, J] = c[J]^T B^{-1}A[\ast, J] = c[J]^T. \quad \square$$

Lemma 7 implies that $k \notin J$, since $c_k - z_k < 0$.

Lemma 8. $Y[\ast, J] = I$. Let $J = [j_1, j_2, \dots, j_m]$. Then $Y[i, j_p] = \begin{cases} 1 & \text{if } p = i \\ 0 & \text{if } p \neq i \end{cases}$.

Proof.

$$Y[\ast, J] = (B^{-1}A)[\ast, J] = B^{-1}A[\ast, J] = B^{-1}B = I.$$

$$Y[i, j_p] = Y[\ast, J][i, p] = I[i, p] = \begin{cases} 1 & \text{if } p = i \\ 0 & \text{if } p \neq i \end{cases}. \quad \square$$

We will now show that the simplex algorithm moves in the direction y in each iteration, and y is a direction in the nullspace of A in which the cost $c^T y$ reduces.

Lemma 9. $Yy = Ay = 0$.

Proof.

$$\begin{aligned}(Yy)_i &= \sum_{j=1}^n Y[i, j]y_j = \sum_{p=1}^m Y[i, j_p]y_{j_p} + Y[i, k]y_k \\ &= y_{j_i} + Y[i, k]y_k = -Y[i, k] + Y[i, k] = 0.\end{aligned}$$

$$Ay = B^{-1}Yy = B^{-1}0 = 0. \quad \square$$

Lemma 10. $c^T y = c_k - z_k < 0$.

Proof.

$$\begin{aligned}c^T y &= \sum_{j=1}^n c_j y_j = c_k y_k + \sum_{p=1}^m c_{j_p} y_{j_p} = c_k - \sum_{p=1}^m c_{j_p} Y[p, k] \\ &= c_k - \sum_{p=1}^m Y^T[k, p]c[J]_p = c_k - (Y^T c[J])_k = c_k - z_k < 0. \quad \square\end{aligned}$$

Theorem 11. If `naiveSimplex` outputs $(\text{unbounded}, \hat{x}, y)$, then the LP's cost reduces along the ray $\{\hat{x} + \lambda y : \lambda \geq 0\}$ and the ray is feasible, which implies that the LP is unbounded.

Proof. Since `naiveSimplex` didn't fail at Lines 3 and 5, we know that $\text{rank}(B) = m$ and $\bar{b} \geq 0$. Hence, J is a feasible basis. So, by Lemma 4, we know that $\hat{x} = \text{solve}(J)$ is a BFS of the LP.

By Lemma 9, we know that $Ay = 0$. Hence, $A(\hat{x} + \lambda y) = A\hat{x} = b$. Since `naiveSimplex` returned $(\text{unbounded}, \hat{x}, y)$, we get that $Y[*, k] \leq 0$ (by Line 12). Hence, $y \geq 0$ and so $\hat{x} + \lambda y \geq \hat{x} \geq 0$. Hence, $\hat{x} + \lambda y$ is feasible for the LP for all $\lambda \geq 0$.

By Lemma 10, we know that $c^T y < 0$. Hence, moving along the ray will reduce cost indefinitely. This implies that the LP is unbounded. \square

Suppose `naiveSimplex` doesn't return an output in an iteration. Then it will change J to, say, \tilde{J} in that iteration (at Line 17). We will show that \tilde{J} is also a feasible basis of the LP, and hence, `naiveSimplex` will not fail at Lines 3 and 5.

Lemma 12. Suppose `naiveSimplex` changes J to \tilde{J} in an iteration. Then \tilde{J} is a basis of the LP.

Proof. Let $J = [j_1, j_2, \dots, j_m]$. The set of values in \tilde{J} is $J - \{j_r\} \cup \{k\}$. Since $k \notin J$, \tilde{J} has distinct values.

Let a_j be the j^{th} column of A . Let $B = A[*, J]$. Let $\tilde{B} = A[*, \tilde{J}]$. Let $S = \{a_{j_1}, a_{j_2}, \dots, a_{j_m}\}$ be the set of columns of B and let $\tilde{S} = S - \{a_{j_r}\} \cup \{a_k\}$ be the set of columns of \tilde{B} . Since J is a basis, $\text{rank}(B) = m$, so S is a set of linearly independent vectors. Since $|S| = m$, we get that S is a basis of \mathbb{R}^m . Hence, $a_k \in \text{span}(S)$.

Let $a_k = \sum_{i=1}^m \lambda_i a_{j_i}$. Let $\lambda = [\lambda_1, \lambda_2, \dots, \lambda_m]$. Then $B\lambda = \sum_{i=1}^m \lambda_i a_{j_i} = a_k$. Hence, $\lambda = B^{-1}a_k = Y[*, k]$. Since $Y[r, k] > 0$, we get that $\lambda_r > 0$. Hence, by Lemma 2, we get that \tilde{S} is also a basis of \mathbb{R}^m . Hence, $\text{rank}(\tilde{B}) = m$, so \tilde{J} is a basis. \square

Lemma 13. Suppose `naiveSimplex` changes J to \tilde{J} in an iteration. Let $\hat{x} = \text{solve}(J)$ and $\tilde{x} = \hat{x} + \delta y$. Then $\tilde{x} = \text{solve}(\tilde{J})$ and \tilde{J} is a feasible basis.

Proof. By Lemma 9, we get that $Ay = 0$. Hence, $A\tilde{x} = A\hat{x} + \delta(Ay) = A\hat{x} = b$.

If $i \notin J$ or $Y[i, k] \leq 0$, then $y_i \geq 0$, and hence $\tilde{x}_i = \hat{x}_i + \delta y_i \geq \hat{x}_i \geq 0$. Now let $i \in J$ and $Y[i, k] > 0$. Let $J = [j_1, j_2, \dots, j_m]$. Then

$$\delta = \frac{\bar{b}_r}{Y[r, k]} \leq \frac{\bar{b}_i}{Y[i, k]}.$$

$$\implies \tilde{x}_{j_i} = \hat{x}_{j_i} + \delta y_{j_i} = \bar{b}_i - \delta Y[i, k] \geq 0.$$

Hence, $\tilde{x} \geq 0$. Therefore, \tilde{x} is feasible for the LP.

Let $i \in [n] - \tilde{J}$. If $i = j_r$, then

$$\tilde{x}_i = \hat{x}_{j_r} + \delta y_{j_r} = \bar{b}_r - \delta Y[r, k] = 0.$$

If $i \in [n] - J - \{k\}$, then $\tilde{x}_i = \hat{x}_i + \delta y_i = 0 + \delta 0 = 0$. Hence, $\tilde{x}_i = 0$ when $i \notin \tilde{J}$. Let $\tilde{B} := A[\ast, \tilde{J}]$. Then

$$b = A\tilde{x} = A[\ast, \tilde{J}]\tilde{x}[\tilde{J}] = \tilde{B}\tilde{x}[\tilde{J}].$$

By Lemma 12, \tilde{J} is a basis, so \tilde{B} is invertible. Hence, $\tilde{x}[\tilde{J}] = \tilde{B}^{-1}b$. Furthermore, $\tilde{x}[[n] - \tilde{J}] = 0$, so $\tilde{x} = \text{solve}(\tilde{J})$. Since $\tilde{x} \geq 0$, we get that $\tilde{B}^{-1}b \geq 0$. Hence, \tilde{J} is a feasible basis. \square

4 The Tableau Method and the Revised Simplex method

The naive simplex method has a large running time of $O(m^2(m+n))$, since we compute B^{-1} , Y , \bar{b} and z afresh in each iteration. The tableau method and the revised simplex method are two ways to get around this problem.

Let J be a feasible basis of the LP. Let $B = A[\ast, J]$, $Y = B^{-1}A$, $\bar{b} = B^{-1}b$ and $z = Y^T c[J]$. Suppose $c_k - z_k < 0$ for some $k \in [n] - \tilde{J}$ and $Y[r, k] > 0$ for some $r \in [m]$. Assume without loss of generality that $r = \text{argmin}_{i \in [m]: Y[i, k] > 0} \frac{\bar{b}_i}{Y[i, k]}$. Let \tilde{J} be a sequence obtained by changing the r^{th} element of J to k . By Lemma 13, \tilde{J} is a feasible basis. Let $\tilde{B} = A[\ast, \tilde{J}]$, $\tilde{Y} = \tilde{B}^{-1}A$, $\tilde{\bar{b}} = \tilde{B}^{-1}b$ and $\tilde{z} = \tilde{Y}^T c[\tilde{J}]$. We will now see how to compute \tilde{Y} , \tilde{z} and $\tilde{\bar{b}}$ from \tilde{Y} , z and \bar{b} .

Define the matrix \hat{Y} as

$$\hat{Y}[i, j] = \begin{cases} \frac{Y[r, j]}{Y[r, k]} & \text{if } i = r \\ Y[i, j] - \frac{Y[i, k]}{Y[r, k]}Y[r, j] & \text{if } i \neq r \end{cases}.$$

Note that \hat{Y} is obtained from Y by elementary row operations. This is called *pivoting*, and $Y[r, \ast]$ is a column vector where the r^{th} entry is 1 and the others are 0. Let R be the

matrix of these row operations. Then $\widehat{Y} = RY$. We can find R by applying these row operations to the m -by- m identity matrix.

$$R[i, j] = \begin{cases} \frac{I[r, j]}{Y[r, k]} & \text{if } i = r \\ I[i, j] - \frac{Y[i, k]}{Y[r, k]} I[r, j] & \text{if } i \neq r \end{cases}$$

$$= \begin{cases} \frac{1}{Y[r, k]} & \text{if } i = r = j \\ -\frac{Y[i, k]}{Y[r, k]} & \text{if } i \neq r \wedge j = r \\ 1 & \text{if } i \neq r \wedge j = i \\ 0 & \text{if } j \notin \{i, r\} \end{cases}$$

Lemma 14. $\widetilde{B}^{-1} = RB^{-1}$ and $\widetilde{Y} = RY$ and $\widetilde{b} = R\bar{b}$.

Proof. Let $J = [j_1, j_2, \dots, j_m]$. $\widetilde{J} = J - \{j_r\} \cup \{k\}$. By Lemma 8, we get that $Y[*, J] = \widetilde{Y}[*], \widetilde{J}] = I$. We will try to show that $\widehat{Y}[*], \widetilde{J}] = I$.

Let $p, q \in [m] - \{r\}$.

$$\widehat{Y}[*], \widetilde{J}][r, r] = \widehat{Y}[r, \widetilde{J}[r]] = \widehat{Y}[r, k] = 1.$$

$$\widehat{Y}[*], \widetilde{J}][r, q] = \widehat{Y}[r, \widetilde{J}[q]] = \widehat{Y}[r, j_q] = \frac{Y[r, j_q]}{Y[r, k]} = 0. \quad (\text{by Lemma 8})$$

$$\widehat{Y}[*], \widetilde{J}][p, r] = \widehat{Y}[p, \widetilde{J}[r]] = \widehat{Y}[p, k] = Y[p, k] - \frac{Y[p, k]}{Y[r, k]} Y[r, k] = 0.$$

$$\begin{aligned} \widehat{Y}[*], \widetilde{J}][p, q] &= \widehat{Y}[p, \widetilde{J}[q]] = \widehat{Y}[p, j_q] = Y[p, j_q] - \frac{Y[p, k]}{Y[r, k]} Y[r, j_q] = Y[p, j_q] \\ &= \begin{cases} 1 & \text{if } p = q \\ 0 & \text{otherwise} \end{cases}. \end{aligned} \quad (\text{by Lemma 8})$$

Hence, $\widehat{Y}[*], \widetilde{J}] = I$.

$$I = \widehat{Y}[*], \widetilde{J}] = (RB^{-1}A)[*, \widetilde{J}] = RB^{-1}A[*, \widetilde{J}] = RB^{-1}\widetilde{B}.$$

Hence, $\widetilde{B}^{-1} = RB^{-1}$.

$$\widetilde{Y} = \widetilde{B}^{-1}A = RB^{-1}A = RY.$$

$$\widetilde{b} = \widetilde{B}^{-1}b = RB^{-1}b = R\bar{b}. \quad \square$$

Define $\widehat{z} \in \mathbb{R}^n$ and η as

$$\widehat{z}_j = z_j + \frac{c_k - z_k}{Y[r, k]} Y[r, j] \quad \eta = c[J]^T \bar{b} + \frac{c_k - z_k}{Y[r, k]} \bar{b}_r.$$

Lemma 15. $\hat{z} = \tilde{z}$ and $\eta = c[\tilde{J}]^T \tilde{b}$.

Proof. Let $J = [j_1, j_2, \dots, j_m]$. Then $\tilde{J} = J - \{j_r\} \cup \{k\}$. Let $i \in [m] - \{r\}$. Then

$$\hat{z}[\tilde{J}]_i = \hat{z}_{j_i} = z_{j_i} + \frac{c_k - z_k}{Y[r, k]} Y[r, j_i] = z_{j_i}.$$

By Lemma 8, we get $Y[r, j_i] = 0$. By Lemma 7, we get $z_{j_i} = c_{j_i}$. Hence, $\hat{z}[\tilde{J}]_i = c_{j_i} = c[\tilde{J}]_i$.

$$\hat{z}[\tilde{J}]_r = \hat{z}_k = z_k + \frac{c_k - z_k}{Y[r, k]} Y[r, k] = c_k = c[\tilde{J}]_r.$$

Hence, $\hat{z}[\tilde{J}] = c[\tilde{J}]$.

$$Y[r, *] = (B^{-1}A)[r, *] = B^{-1}[r, *]A.$$

$$\bar{b}_r = (B^{-1}b)_r = B^{-1}[r, *]b.$$

Let $\alpha = (c_k - z_k)/Y[r, k]$. Then

$$\hat{z}^T = z^T + \alpha Y[r, *] = c[J]^T B^{-1}A + \alpha B^{-1}[r, *]A.$$

$$\eta = c[J]^T \bar{b} + \alpha \bar{b}_r = c[J]^T B^{-1}b + \alpha B^{-1}[r, *]b.$$

Let $u^T = c[J]^T B^{-1} + \alpha B^{-1}[r, *]$. Then $\hat{z}^T = u^T A$ and $\eta = u^T b$.

$$c[\tilde{J}]^T = \hat{z}[\tilde{J}]^T = (u^T A)[\tilde{J}] = u^T A[\tilde{J}] = u^T \tilde{B}.$$

Hence, $u^T = c[\tilde{J}]^T \tilde{B}^{-1}$. So, $\hat{z} = c[\tilde{J}]^T \tilde{B}^{-1}A = c[\tilde{J}]^T \tilde{Y} = \tilde{z}$ and $\eta = c[\tilde{J}]^T \tilde{B}^{-1}b = c[\tilde{J}]^T \tilde{b}$. \square

4.1 Tableau method

Note that $c[J]^T \bar{b} = c^T \text{solve}(J)$. In the tableau method, we compute B^{-1} , Y , \bar{b} , z and $c[J]^T \bar{b}$ in the first iteration. In subsequent iterations, we update Y and \bar{b} by applying elementary row operations given by R (see Lemma 14), and update z and $c[J]^T \bar{b}$ as per Lemma 15. All of these operations can be done together as a pivoting operation on the following matrix, called the tableau:

$$\begin{bmatrix} c - z & -c[J]^T \bar{b} \\ Y & \bar{b} \end{bmatrix}.$$

The time per iteration is, therefore, $O(mn)$. We can reduce this to $O(m(n - m))$ if we observe that when we pivot on row r and column k , then $m - 1$ entries in $Y[r, *]$ are 0 (by Lemma 8). The space complexity is $O(mn)$.

4.2 Revised simplex method

In the revised simplex method, we compute B^{-1} in the first iteration. Henceforth, we will assume that B^{-1} is available in the beginning of each iteration and we need to update it at the end of each iteration.

Compute $c[J]^T B^{-1}$ by multiplying $c[J]^T$ and B^{-1} . Then we iterate over $j \in [n] - \tilde{J}$, and compute $z_j = (c[J]^T B^{-1})A[:, j]$. We stop iterating when we find a suitable $k \in [n] - \tilde{J}$ such that $c_k - z_k < 0$, or if $c_j - z_j \geq 0$ for all $j \in [n] - \tilde{J}$.

Next, we compute $u = B^{-1}A[:, k]$ and $\bar{b} = B^{-1}b$. Note that $u = Y[:, k]$. Then we continue from Line 11 onwards (i.e., compute y , δ and r , and update \tilde{J}). At the end of the iteration, we can update B^{-1} using row operations as per Lemma 14. This is possible since R is defined by u .

The time taken is $O(m(t + m))$, where t is the number of variables that need to be considered till we find k . Note that $t \leq n - m$. The space complexity (in addition to storing the input) is $O(m^2)$.
